A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	<i>M</i> -ary Signal Sets	Message Sequence ●oo ○○ ○○○○○○○ ○○○○○○○○○○

# Introduction

- We compare methods for transmitting a sequence of bits.
- We will see that the performance of these methods varies significantly.
- New perspective:
  - Focus on messages, i.e., sequences of bits
  - Entire message must be received correctly
- Main Result: It is possible to achieve error free communications as long as SNR is good enough and data rate is not too high.

essage Sequence

## **Problem Statement**

#### Problem:

- K bits must be transmitted in T seconds.
- Available power is limited to P.

#### Questions:

- What method achieves the lowest probability of error?
- Is error-free communications possible?

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 000000000	00000000 00000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	<b>00</b> ● 00 000000 0000000000

#### **Parameters**

**Data Rate:** 

$$R=rac{K}{T}$$
 (bits/s)

- entire transmission takes T seconds
- ► *K* bits are sent over *T* seconds
- implicit assumption: bits are equally likely.
- Power and energy: transmitted signal s(t) has power P and energy E

$$P = \frac{1}{T} \int_0^T |s(t)|^2 dt = \frac{E}{T}$$

- Entire transmitted signal s(t) is of duration T.
- Note, bit energy is given by

$$E_b = rac{E}{\kappa} = rac{PT}{\kappa} = rac{P}{R}.$$

# **Bit-by-bit Signaling**

- Transmit K bit as a sequence of "one-shot" BPSK signals.
- $\blacktriangleright$  *K* = *RT* bits to be transmitted.
- Energy per bit  $E_b$   $(E_b = \frac{E}{K})$ .
- Consider, signals of the form

$$s(t) = \sum_{k=0}^{K-1} \sqrt{E_b} s_k p(t - k/R)$$

*s<sub>k</sub>* ∈ {±1}
 *p*(*t*) is a pulse of duration 1/*R* = *T*/*K* and ||*p*(*t*)||<sup>2</sup> = 1.
 Question: What is the probability that any transmission error occurs?

# In other words, the transmission is not received without error.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	00000000 000000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000	000 ⊙● 000000 000000000

# Error Probability for Bit-by-Bit Signaling

We can consider the entire message as a single K-dimensional signal set.

Signals are at the vertices of a *K*-dimensional hypercube.

$$\Pr\{e\} = 1 - \left(1 - Q\left(\frac{2E_b}{N_0}\right)\right)^K$$
$$= 1 - \left(1 - Q\left(\frac{2P}{RN_0}\right)\right)^{RT}$$

- Note, for any finite  $P/N_0$  and R, the error rate will always tend to 1 as  $T \rightarrow \infty$ .
  - Error-free transmission is *not* possible with bit-by-bit signaling.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	0000000 00000000 0000000	00 000000000000 00000000 0000000	00 00000000 000000000 00000000 00000000	000 00 ●00000 000000000

# Block-Orthogonal Signaling

- Again,
  - $\blacktriangleright$  K = RT bits are transmitted in T seconds.
  - Energy per bit  $E_b = \frac{P}{R}$ .

Signal set (Pulse-position modulation — PPM)

$$s_k(t) = \sqrt{E}p(t - kT/2^K)$$
 for  $k = 0, 1, ..., 2^K - 1$ .

where p(t) is of duration  $T/2^{K}$ ,  $E = KE_{b}$ , and  $\|p(t)\|^{2} = 1$ .

Alternative signal set (Frequency Shift Keying — FSK)

$$s_k(t) = \sqrt{\frac{2E}{T}} \cos(2\pi (f_c + k/T)t)$$
 for  $k = 0, 1, ..., 2^K - 1$ .

- Signal set consists of  $M = 2^{K}$  signals
  - each signal conveys K bits,
  - each signal occupies one of the K dimensions.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	00000000 00000000 00000000	00 000000000000 00000000 0000000	00 0000000 000000000 00000000 00000000	000 00 000000 000000000

# **Union Bound**

- The error probability for block-orthogonal signaling cannot be computed in closed form.
- At high and moderate SNR, the error probability is well approximated by the union bound.
  - Each signal has  $M 1 = 2^{K} 1$  nearest neighbors.
  - The distance between neighbors is  $d_{\min} = \sqrt{2E} = \sqrt{2KE_b}$ .
- Union bound

$$\Pr\{e\} \le (2^{K} - 1)Q\left(\sqrt{\frac{KE_{b}}{N_{0}}}\right)$$
$$= (2^{RT} - 1)Q\left(\sqrt{\frac{PT}{N_{0}}}\right)$$

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	00000000 00000000 0000000	00 000000000000 00000000 0000000	00 0000000 000000000 00000000 00000000	000 00 000000 000000000

## Bounding the Union Bound

► To gain further insight, we bound

$$Q(x) \leq \frac{1}{2} \exp(-x^2/2) \leq \exp(-x^2/2).$$

Then,

$$\Pr\{e\} \le (2^{RT} - 1)Q\left(\sqrt{\frac{PT}{N_0}}\right)$$
$$\le 2^{RT} \exp\left(-\frac{PT}{2N_0}\right)$$
$$= \exp\left(-T\left(\frac{P}{2N_0} - R\ln 2\right)\right).$$

• Hence,  $\Pr\{e\} \to 0$  as  $T \to \infty!$ 

• As long as 
$$R < \frac{1}{\ln 2} \frac{P}{2N_0}$$
.

Error-free transmission is possible!

## Reality-Check: Bandwidth

• **Bit-by-bit Signaling:** Pulse-width: T/K = 1/R.

- Bandwidth is approximately equal to B = R.
- Also, number of dimensions K = RT.
- **Block-orthogonal:** Pulse width:  $T/2^{K} = T/2^{RT}$ .
  - ► Bandwidth is approximately equal to  $B = 2^{RT} / T$ .
  - Number of dimensions is  $2^{K} = 2^{RT}$ .
- Bandwidth for block-orthogonal signaling grows exponentially with the number of bits K.
  - Not practical for moderate to large blocks of bits.

A Simple Example o ooooo oooooooooo	Binary Hypothesis Testing	Optimal Receiver Frontend	<i>M</i> -ary Signal Sets oo oooooooo oooooooooooo	Message Sequence
	0000000	000000000000000000000000000000000000000	00000000000 0000000 000000000000000000	000000000000000000000000000000000000000

## The Dimensionality Theorem

- The relationship between bandwidth B and the number of dimensions is summarized by the *dimensionality theorem*:
  - The number of dimensions D available over an interval od duration T is limited by the bandwidth B

$$D \leq B \cdot T$$

- The theorem implies:
  - A signal occupying D dimensions over T seconds requires bandwidth

$$B \ge \frac{D}{T}$$

0 00000 00000000	00000000 000000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 000000000

# An Ideal Signal Set

- An ideal signal set combines the aspects of our two example signal sets:
  - $\triangleright$  Pr{*e*}-behavior like block orthogonal signaling

 $\lim_{T\to\infty} \Pr\{e\} = 0.$ 

Bandwidth behavior like bit-by-bit signaling

$$B = \frac{D}{T} = \text{constant}.$$

• Thus, 
$$D = BT \rightarrow \infty$$
 as  $T \rightarrow \infty$ .

Question: Does such a signal set exist?

0 00000 00000000	00000000 00000000 00000000	00 000000000000 00000000 0000000	00 00000000 000000000 00000000 00000000	000 00 000000 •00000000

#### **Towards Channel Capacity**

#### Given:

- bandwidth  $B = \frac{D}{T}$ , where T is the duration of the transmission.
- power P
- ▶ Noise power spectral density  $\frac{N_0}{2}$
- Question: What is the highest data rate R that allows error-free transmission with the above constraints?
  - ► We are transmitting *RT* bits
  - Therefore, we need  $M = 2^{RT}$  signals.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	<i>M</i> -ary Signal Sets oo oooooooo oooooooooooooooooooooooo	Message Sequence
		000000	00000000 00000000000000000000000000000	

# Signal Set

• Our signal set consists of  $M = 2^{RT}$  signals of the form

$$s_n(t) = \sum_{k=0}^{D-1} X_{n,k} p(t - kT/D)$$

where

- p(t) are pulses of duration T/D, i.e., of bandwidth B = D/T.
- ► Also,  $||p(t)||^2 = 1$ .
- Each signal  $s_n(t)$  is defined by a length-*D* vector  $\vec{X_n} = \{X\}_{n,k}$ .
- We are looking to find  $M = 2^{RT}$  length-*D* vectors  $\vec{X}$  that lead to good error properties.
- Note that the signals p(t kT/D) form an orthonormal basis with *D* dimensions.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequ
0 00000 000000000	00000000 000000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 00000000000000

# **Receiver Frontend**

- The receiver frontend consists of a matched filter for p(t) followed by a sampler at times kT/D.
  - ► I.e., the frontend projects the received signal onto the orthonormal basis functions p(t kT/D).
- The vector  $\vec{R}$  of matched filter outputs has elements

$$R_k = \langle R_t, p(t-kT/D) \rangle$$
  $k = 0, 1, \ldots, D-1$ 

- Conditional on  $s_n(t)$  was sent,  $\vec{R} \sim N(\vec{X}_n, \frac{N_o}{2}I)$ .
- The optimum receiver selects the signal  $s_n$  that's closest to  $\vec{R}$ .

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	0000000 00000000 0000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 00000000

# **Conditional Error Probability**

- ▶ When, the signal  $s_n(t)$  was sent then  $\vec{R} \sim N(\vec{X}_n, \frac{N_o}{2}I)$ .
- As the number of dimensions *D* increases, the vector  $\vec{R}$  lies within a *D*-dimensional sphere with center  $\vec{X}_k$  and radius

 $\sqrt{D\frac{N_0}{2}}$  with very high probability:  $1 - e^{-D}$ , i.e.,  $P_e = e^{-D}$ .

Important: We allow the radius of the decoding spheres to grow with the number of dimensions D.

▶ This ensures that  $P_e \rightarrow 0$  as  $D = BT \rightarrow \infty$ .

- We call the spheres of radius  $\sqrt{D\frac{N_0}{2}}$  around each signal point *decoding spheres*.
  - The decoding spheres will be part of the decision regions for each point.

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 000000000	00000000 000000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 000000000

# **Power Constraint**

• The power for signal  $s_n(t)$  must satisfy

$$\frac{1}{T}\int_0^T s_n^2(t) dt = \frac{1}{T}\sum_{k=0}^{D-1} |X_{n,k}|^2 = \frac{1}{T} \|\vec{X}_n\|^2 \le P.$$

• Therefore, 
$$\|\vec{X}_n\|^2 \leq PT$$

- Insights:
  - The transmitted signals lie in a sphere of radius  $\sqrt{PT}$ .
  - The observed signals must lie in a large sphere of radius  $\sqrt{PT + D\frac{N_0}{2}}$ .

Question: How many decoding spheres can we have and still meet the power constraint?

	lessage Sequence
00000000000000000	

# Capacity

- Each decoding sphere has volume  $K_D(\sqrt{D\frac{N_0}{2}})^{\prime}$ .
- The volume of the sphere containing the observed signals is  $K_D(\sqrt{PT + D\frac{N_0}{2}})^D$ 
  - ►  $K_D$  is a constant that depends only on the number of dimensions D, e.g.,  $K_3 = \frac{4\pi}{3}$ .
- The number of decoding spheres that fit into the the power sphere is (upper) bounded by the ratio of the volumes

$$\frac{K_D\left(\sqrt{PT+D\frac{N_0}{2}}\right)^D}{K_D\left(\sqrt{D\frac{N_0}{2}}\right)^D}$$

A Simple Example o ooooo oooooooooo	Binary Hypothesis Testing	Optimal Receiver Frontend	00 00000000 0000000000	Message Sequence
		000000	00000000 00000000000000000000000000000	0000000000

# Capacity

Since the number of signals  $M = 2^{RT}$  equals the number of decoding spheres, it follows that error free communications is possible (in the limit as  $D = BT \rightarrow \infty$ ) if

$$M = 2^{RT} < \frac{\left(\sqrt{PT + D\frac{N_0}{2}}\right)^D}{\left(\sqrt{D\frac{N_0}{2}}\right)^D}$$

or

$$R < \frac{D}{2T}\log_2(1 + \frac{PT}{DN_0/2}) = \frac{B}{2}\log_2(1 + \frac{P}{BN_0/2}).$$

Note, if we allow *complex valued* signals, then  $R < B \log_2(1 + \frac{P}{BN_0})$ .

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 00000000	00000000 00000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 000000000000000000000000

#### Illustration: 2-bit Messages

Consider two different ways of transmitting two bits:

- QPSK
- rate 2/3 block code and BPSK modulation
- Compare the probability of at least one bit error
  - constant  $\frac{E_b}{N_0}$ .

A Simple Example	Binary Hypothesis Testing	Optimal Receiver Frontend	M-ary Signal Sets	Message Sequence
0 00000 000000000	00000000 000000000 00000000	00 000000000000 00000000 0000000	00 00000000 0000000000 00000000 0000000	000 00 000000 00000000000000000000000

# **QPSK**

- energy efficiency  $\eta_u = 4$
- (symbol) error rate

$$\mathsf{P}_{e} \leq 2\mathsf{Q}\left(\sqrt{rac{2E_{b}}{N_{0}}}
ight)$$

	A Simple Example o ooooo oooooooooo	Binary Hypothesis Testing	Optimal Receiver Frontend	00 00000000 0000000000 000000000	Message Sequence
--	---	---------------------------	---------------------------	---	------------------

## Benefit of a Simple Code

The block code maps two bits to sequence of three BPSK symbols as follows:

00 :{1, 1, 1} 10 :{-1, 1, -1}

$$01: \{1, -1, -1\}$$
  
 $11: \{-1, -1, 1\}$ 

For this signal set:

- energy efficiency  $\eta_c = \frac{16}{3}$
- (symbol) error rate

$$P_e \leq 3Q\left(\sqrt{\frac{8E_b}{3N_0}}
ight)$$

Coding gain:

$$\frac{\eta_c}{\eta_u} = \frac{16/3}{4} = \frac{4}{3} \approx 1 \text{dB}$$
